CHILDHOOD IMMUNIZATION: PUBLIC HEALTH IMPACT, SAFETY, AND REMAINING CHALLENGES

Scientific supervisor: **Asatullayev Rustamjon Bakhtiyarovich**

Student: **Muslima Vaxobova**

Abstract: **Background:** Routine childhood immunization is among the most effective public health interventions, yet coverage gaps and vaccine hesitancy sustain outbreaks of preventable disease. **Objective:** To summarize evidence on the impact, safety, and coverage of childhood vaccination programs. **Methods:** Narrative review of landmark studies, meta-analyses, and World Health Organization (WHO) and UNICEF reports. **Results:** Immunization averts an estimated 3.5–5 million deaths annually and has substantially reduced child mortality since the Expanded Programme on Immunization began in 1974. Large cohort studies and meta-analyses find no association between vaccines and autism. Serious adverse events are rare. Global coverage remains uneven, with millions of children receiving no routine doses. **Conclusion:** Sustaining high coverage requires strong health systems, transparent communication, and trust in health workers.

Keywords: childhood immunization; vaccine safety; herd immunity; vaccine hesitancy; vaccine-preventable diseases

1. Introduction

Vaccination has transformed child health. Smallpox has been eradicated, poliomyelitis is close to eradication, and diseases such as measles, diphtheria, and pertussis, once leading causes of childhood death, are now largely preventable [1,3]. Immunization programs protect vaccinated individuals directly and unvaccinated individuals indirectly through herd immunity. For highly contagious diseases such as measles, interrupting transmission generally requires coverage of at least 95% with two doses [8].

Despite these achievements, the WHO Immunization Agenda 2030 highlights persistent inequities in access and the threat of declining public confidence [6]. This review summarizes the evidence on impact, safety, and coverage to inform clinicians and policymakers.

2. Methods

This is a narrative review, not a systematic one. Sources were selected for relevance and influence: peer-reviewed modelling studies, meta-analyses, national cohort studies, and WHO/UNICEF estimates of national immunization coverage. No formal search protocol or quality scoring was applied, so selection bias is possible.

3. Results

3.1 Public health impact

WHO estimates that immunization currently prevents 3.5–5 million deaths each year from diphtheria, tetanus, pertussis, influenza, and measles [6]. A modelling study covering 50 years of the Expanded Programme on Immunization attributed an estimated 154 million saved lives to vaccination, most of them infants [7]. In the United States, routine childhood vaccination of one birth cohort was estimated to prevent about 20 million illnesses and 42,000 early deaths over the lifetimes of those children, with substantial net economic savings [2].

3.2 Safety

Vaccines undergo extensive pre-licensure trials and continuous post-marketing surveillance. Common reactions are mild and short-lived: local pain, redness, and low-grade fever. Anaphylaxis is rare, occurring on the order of one case per million doses [8]. The claim that the measles-mumps-rubella (MMR) vaccine causes autism has been tested repeatedly. A meta-analysis of studies including more than 1.2 million children found no association between vaccination and autism or autism spectrum disorder [4]. A Danish

nationwide cohort of 657,461 children reached the same conclusion, including among children at higher risk [5].

3.3 Coverage and inequity

According to WHO/UNICEF estimates, global coverage with the third dose of diphtheria-tetanus-pertussis vaccine (DTP3) was about 84% in 2023, and roughly 14.5 million children received no routine vaccine doses at all [6]. These “zero-dose” children are concentrated in conflict-affected, remote, and urban-poor settings. Hesitancy adds to this gap; a systematic review identified distrust of institutions, safety concerns, and misinformation as recurring drivers across regions [9].

4. Discussion

The evidence consistently shows that the benefits of childhood vaccination far exceed its risks. The main threat today is not vaccine failure but under-delivery. Outbreaks occur where coverage falls below herd-immunity thresholds, as repeated measles resurgences show. Two strategies are supported by the literature: (1) reaching zero-dose children through outreach, integrated services, and reduced out-of-pocket costs; and (2) building confidence through clear, honest communication about both benefits and rare adverse events, delivered by trusted health workers [9].

Limitations of this review include its narrative design and reliance on modelled estimates, which carry uncertainty. Coverage figures are revised by WHO/UNICEF each year and should be checked against the latest release. National schedules also differ, so local clinical decisions should follow current ministry of health guidance.

5. Conclusion

Childhood immunization prevents millions of deaths and disabilities each year and has an established safety record. Closing coverage gaps and maintaining public trust are the priorities for the coming decade.
